

# Recent study of fission in inverse kinematics

*Oleg B. Tarasov (NSCL/MSU)*

- Introduction
- GANIL: Fusion-Fission
- MSU: Abrasion-Fission
- MSU: Abrasion-Ablation
- Couple words for ...
- Summary

- ❑ Nowadays, fission is widely used to produce rare neutron-rich nuclei. :
  - \* in-flight fission (abrasion-fission, Coulomb fission)
  - \* spallation reactions (ISOL technique) at thick Uranium targets
- ❑ Important issue of these both techniques is the inability to produce neutron-rich fragments with  $Z > 55$  due to small production abrasion-fission cross sections.

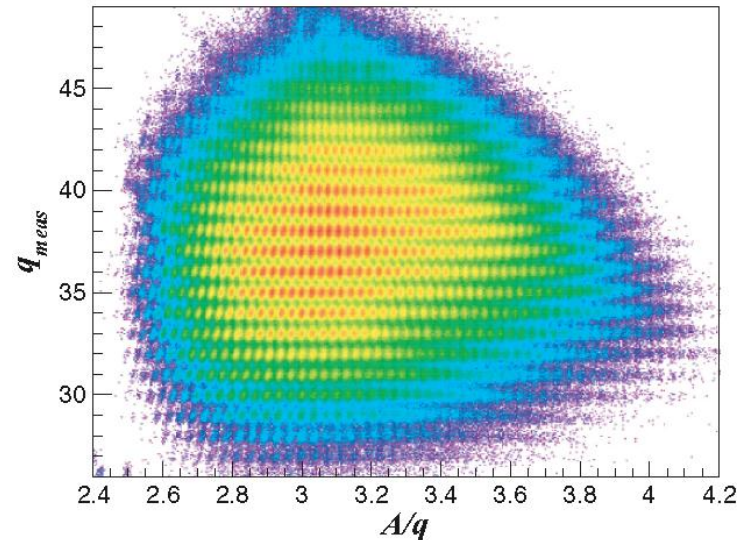

Using fusion-fission reactions, the fissile nucleus becomes heavy than projectile (Uranium)

Inverse kinematics of low energy reactions?

- ❑ VAMOS experiments to measure fission fragment yields from the reaction of  $^{238}\text{U}$  with  $^{12}\text{C}$  near the Coulomb barrier demonstrated the advantages of inverse kinematics to study production mechanisms [1], and to investigate fission fragments properties [2].
- ❑ However, in order to explore properties of very neutron rich isotopes produced in this way it is necessary to separate isotopes of interest from undesirable products.

**How to produce heavy fusion-fission beams with separators ?**

A model [1] for fast calculations of fusion–fission fragment cross sections has been developed in LISE++ [2] based on already existent analytical solutions: fusion–evaporation and fission fragment production models.

### Main features of the model:

- Production cross-section of fragments
- Kinematics of reaction products
- Spectrometer tuning to the fragment of interest optimized on maximal yield (or on good purification)

Advantages of in-flight fusion-fission to explore neutron-rich  $55 < Z < 75$  region are comparing to AF & CF:

- the heavier fissile nucleus competing with abrasion-fission ( $Z < 92$ ),
- the higher excitation energy of a fissile nucleus competing with Coulomb fission of the  $^{238}\text{U}$  primary beam.

### Open Questions:

- What is optimal conditions, for example the energy of primary beam, the target material, thickness and so on?
- How reliable are simulations? Intensities, purification?
- What are contributions from other reaction mechanisms?
- Separation, Identification, Resolution?

[2] O. B. T. and D. Bazin, NIM B 266, 4657 (2008).

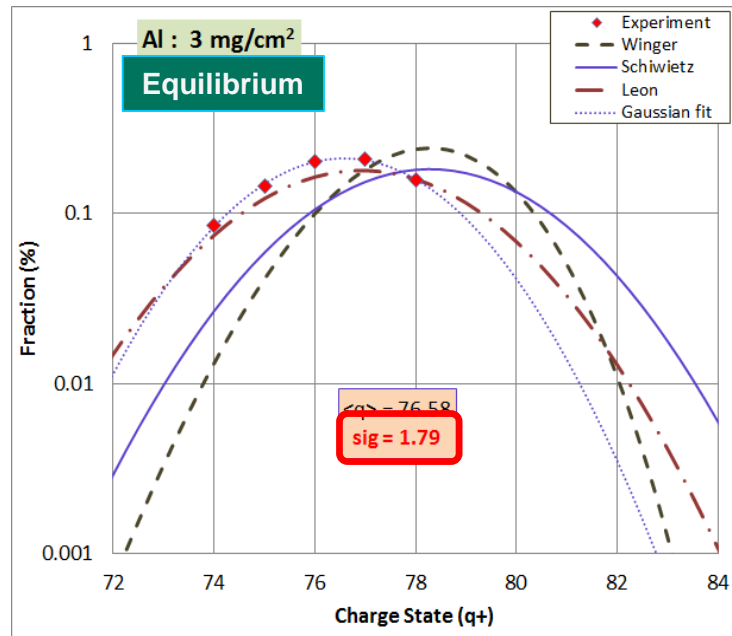

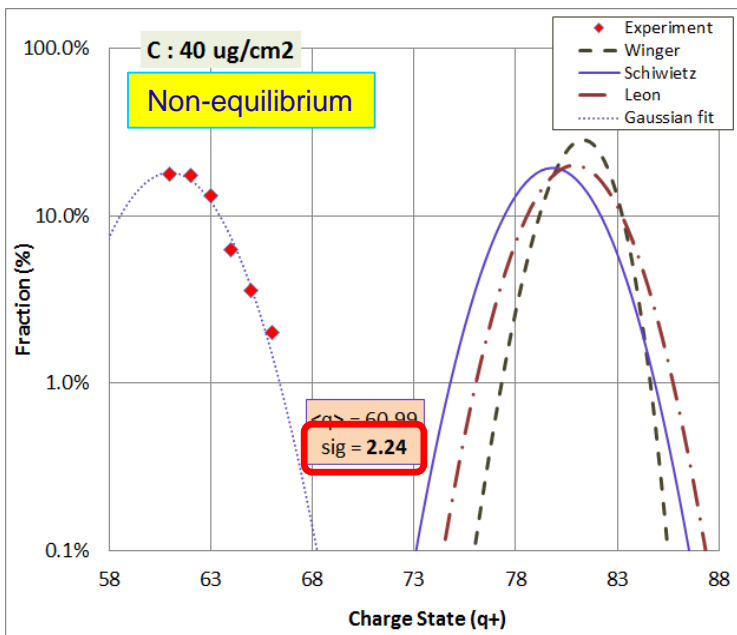

Fig. Two-dimensional yield plot for fragments produced in the  $^{238}\text{U}$  (20 MeV/u, 1pnA) + D (12 mg/cm<sup>2</sup>) reaction and separated by SISSI + Alpha

A experiment to show separation and identification of fusion-fission products has been performed using the LISE3 fragment-separator at GANIL.

- A <sup>238</sup>U beam at 24 MeV/u with a typical intensity of 10<sup>9</sup> pps, was used to irradiate a series of beryllium targets and a carbon target.
- The beam was incident at an angle of 3° in order not to overwhelm the detectors with the beam charge states.
- Fragments were detected in a Silicon telescope at the end of the separator. Fission fragments produced by inverse kinematics are identified by ΔE-TKE-Bp-ToF method.
- Two MCP detectors (gallete 31 and gallete 62) were used to measure positions and times.
- Germanium γ-ray detectors were placed near the Si telescope to provide an independent verification of the isotope identification via isomer tagging.

- What charge state model should be used for fragment transmission estimation?
- Based on sigma values and peak positions it is possible to conclude about reaching equilibrium thickness
- The best predictions are given for beam and fragments by A.Leon et al., AD & ND Tables 69 (1998) 217

*This work was done also at GANIL*

- Preliminary detectors calibration with the primary beam,
- Then particle identification has to be proved by gamma from know isomers

Gamma-ray spectrum observed in coincidence with  $^{128}\text{Te}$ . The characteristic gamma lines of 314, 742 and 752 keV sign the decay of the isomeric state of  $T_{1/2} = 370$  ns

The atomic number is determined from the combination of energy loss ( $\Delta E$ ) and time-of-flight (TOF) values according to the Bethe formula:

$$Z \approx \sqrt{\Delta E / \left( \frac{1}{\beta^2} \ln \left( \frac{5930}{1/\beta^2 - 1} \right) - 1 \right)}$$

The fragment mass can be extracted in atomic units from the relativistic formula, where TKE is calculated as a sum of the energy loss values in each of the detectors in a multilayer telescope stopping the products

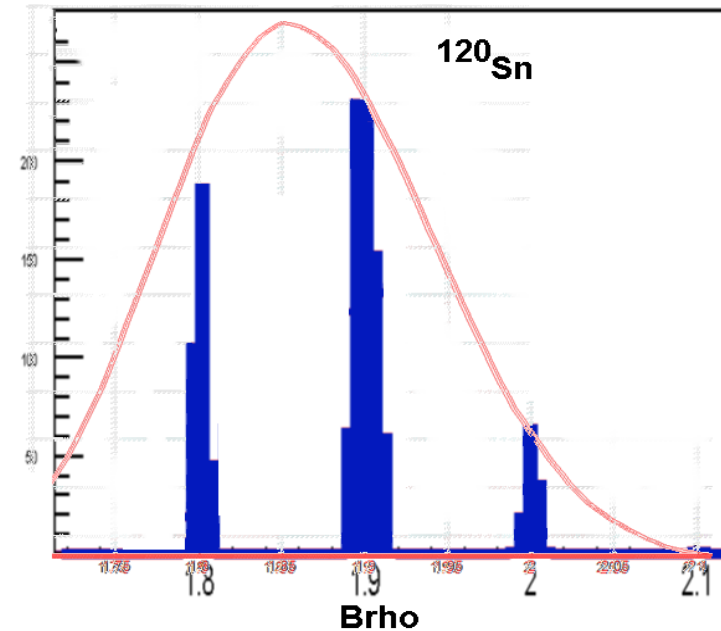

$$A = \frac{TKE}{931.5 \times (\gamma - 1)}$$

The charge state of the ion evaluated from a relation based on the TKE, velocity and magnetic rigidity values:

$$q = 3.33 \times 10^{-3} \frac{TKE \times \beta \gamma}{B\rho(\gamma - 1)}$$

- The LISE++ code has been used for transmission calculations
- A.Leon's charge state and F.Hubert 's energy loss models were used
- Data with 15 mg/cm<sup>2</sup> Be & C targets have been used in analysis
- In the analysis the targets have been divided on 5 slices, results have been summed.  
*It has been done because the LISE++ assumed reaction place in the middle of target*
- *A lot of important updates, improvements, bugs fix were done during this analysis*

<sup>238</sup> U	24	24
Energy	AMeV	AMeV
Target	Be	C
<b>&lt;Z&gt;</b>	<b>48.01</b>	<b>45.75</b>
d<Z>	0.22	0.21
<b>sig(Z)</b>	<b>6.03</b>	<b>6.40</b>
d(sig(Z))	0.17	0.16

Two light targets (A=9 & 12) at the same beam energy, but why so different distributions?

We need a fast analysis of partial cross sections!!

$$\sigma_{ER}^{xn}(E) = \frac{\pi}{k^2} \sum_{l=0}^{\infty} (2l + 1) P_{\text{cont}}(E, l) P_{\text{CN}}(E^*, l) P_{xn}(E^*, l)$$

*Fusion or Quasi-Elastic?* → Transmission probability for a one-dimensional potential barrier

*Compound or Quasi-Fission?* → Probability for compound nucleus formation P\_{CN}

*Capture or Fast Fission?* → Fission barrier vanishing

*Fusion-Evaporation or Fusion-Fission?* → T.PCN,dEx-chan as f(L)

*Capture or Deep-Inelastic?* → Make default

Evaporation settings: 238U(24.0 MeV/u) + 9Be -> 247Cm\* [Ex=201.5 MeV]

Fission properties:
 

- Transmission probability: Classical , Quantum-mechanical  (h\_omega = 5 MeV)
- Nuclear potential: Bass formalism , Wood-Saxon  (V0 = 105 MeV, R0 = 1.12 fm, a = 0.75 fm)
- Calculation: L(Bfis=0) = 67, L critical = 75, L direct (@ Rint) = 85, L max (grazing) = 99.9, L max (LISE) = 100.3

A recent update of low-energy reaction mechanism was performed to simulate the dependence of different reaction channels from angular momentum and qualitatively estimate production cross sections in the case of Fusion-Fission and Fusion-Residue.

Projectile Fragmentation and Abrasion-Fission are dominated reaction mechanisms in LISE++ for rare beam production, where we are developing our own models

Do not hesitate to use Low-Energy reaction computing centers as NRV for more sophisticated solutions with Channel Coupling, Langevin equations and so on

Fusion -> Fission

Evaporation settings: 238U(24.0 MeV/u) + 9Be -> 247Cm\* (Ex=201.5MeV)

Fission properties: **Fission barrier**

Fusion properties:
 

- Transmission probability for a one-dimensional potential barrier:

QE-channel partially goes to Low-excitation fission

## Be-target

## C-target

- Three main channels with earlier discussed parameters were used in fitting
- Reaction positions and widths were used the same in both case during fitting process except FF positions (48 and 49)
- From fitting results it follows, that Fusion-fission dominates in the case of Be-target, and sequential fission in the case of C-target
- New LISE++ partial cross section analysis fairly describes experimental results
- Significant distinction in elemental distributions of fragments produced with two different light target is explained by larger DIC component with C-target due to fission barrier vanishing
- Fusion-Fission mechanism is responsible in both cases for High-Z isotope production (Z>60)**

# Still under analysis ... and again transmission....

Main reaction channels for  $^{238}\text{U}$  (20 MeV/u) on Be & C targets as function of angular momentum

	L ( $B_{fz}=0$ )	L critical	L direct	L max

- The Reverse technique sending experimental data back through a spectrometer to get a momentum vector at the target (Trajectory reconstruction)
- Momentum vector after reaction in target (for example standard S800 technique)
  - Reaction mechanism study
  - Beam spot
  - Angular acceptance vs emittance
- Beam emittance measurement (X,A,Y,B,E)
  - Study of correlations between beam emittance components
- Determination of location of new ions production
  - BigRIPS case : production in the beam-dump
- Benchmarks based on LISE<sup>++</sup> MC apparatus and spectrograph segmentation
  - Beam dynamics visualization
  - Beam optics calculation verification
  - Experimental analysis and calibrations test
- Experiment set-up feedback with LISE<sup>++</sup>
  - Obtaining experimental information by detecting devices in some (or one) locations
  - Retracing up-stream (or down-stream) from detection locations based
  - Analysis, minimization

- The reverse separator technique developed in the LISE++ package\* and coupled with the S800 configuration has been used to study fission mechanism properties.
- Using LISE++ technique allows fragment vectors measured at the final plane of a spectrometer to be replayed through in the backward direction of the spectrometer to reconstruct their trajectories in order to deduce the reaction place and momentum vector.

## v.9.9

- Optics: S & E construction methods
- Extended configurations in LISE<sup>++</sup>
- Compensating dipole
- Multipole : Quadrupole & Sextupole superposition
- TRANSPORT code file import to LISE<sup>++</sup>
- Range Optimizer (Gas cell utility) update

- Extended Configurations

- Regular support routine:
  - user requests, calculation optimization, fix of bugs, interface improvement, Databases and other updates

## v.9.10.345

- Update of Fusion reaction mechanism
- Optics minimization (up to 2<sup>nd</sup> order)
- Reverse configurations: ray trajectory reconstruction
- Radiation Residue Calculator
- ETACHA4 (GUI) (still under construction)
- Others notable
  - Decay Branching Database
  - Ionization energy database & Ion mass calculator
  - Utility "Angular Straggling & Rutherford scattering probabilities in compound"
  - Rutherford scattering of primary beam in target in MC mode
  - FRIB mass tables in the LISE<sup>++</sup> package
  - Second order optics calculations of electric dipole

**Next official version 10 will be released soon : October 2016**

- Fusion-Fission reaction products produced by a  $^{238}\text{U}$  beam at 24 MeV/u on Be and C targets were measured in inverse kinematics by use of the LISE3 fragment separator, and fission and fragmentation products at 80 MeV/u by use the S800 spectrograph and A1900+S800BL separation system.
- The identification of fragments was done using the *dE-TKE-Brho-ToF* method. Germanium gamma-detectors were placed in the focal plane near the Si stopping telescope to provide an independent verification of the isotope identification via isomer tagging.
- The experiments demonstrated excellent resolution, in  $Z$ ,  $A$ , and  $q$  (*fusion-fission  $Z < 60$* ), *projectile fragmentation ( $Z \sim 92$ )*.
- The results demonstrate that a fragment separator can be used to produce radioactive beams using fusion-fission reactions in inverse kinematics, and further that in-flight fusion-fission can become a useful production method to identify new neutron-rich isotopes, investigate their properties and study production mechanisms. Mass, atomic number and charge-state distributions are reported for the two reactions.
- The comparison of the experimental atomic-number and mass distributions combined with the analysis of the isotopic-distributions properties show that between the  $^9\text{Be}$  and the  $^{12}\text{C}$  target, the reaction mechanism changes substantially, evolving from a complete fusion-fission reaction to incomplete fusion or fast fission.
- It has been demonstrated, that the reverse tracking technique can be used as a precise tool to get information for reaction mechanism characteristics.
